Enterprise Lead Management Master Blueprint Part 9 – Enterprise Security, Governance & Compliance

Purpose

Define the security, governance and compliance framework that protects the platform, customer data and operational processes.

Identity & Access Management (IAM)

Implement Single Sign-On where possible, JWT authentication, Multi-Factor Authentication for privileged users and centralized identity management.

Role-Based Access Control (RBAC)

Define roles including Administrator, Sales Manager, Sales Representative, Executive and Read-Only Auditor. Restrict access to APIs, dashboards and data based on least privilege.

API Security

Protect APIs using HTTPS, JWT validation, rate limiting, request validation, API versioning and audit logging. Reject malformed or unauthorized requests.

Data Protection

Encrypt data in transit using TLS and encrypt sensitive data at rest. Mask personally identifiable information where appropriate and secure backups.

Secrets Management

Store API keys, WhatsApp credentials, database credentials and tokens in a secure secrets manager. Never hardcode secrets in source code.

Databricks Governance

Use Unity Catalog for centralized governance. Separate Development, Test and Production catalogs. Apply fine-grained permissions to schemas, tables and views.

Audit & Compliance

Capture immutable audit logs for logins, lead updates, AI decisions, representative assignments, reminders, CSV uploads and administrative actions. Retain logs according to business policy.

Security Monitoring

Monitor authentication failures, API abuse, suspicious activity, failed pipeline executions, unusual data access patterns and infrastructure health. Configure automated alerts.

Business Continuity

Document incident response, disaster recovery, backup validation, periodic access reviews, vulnerability assessments and security testing before every production release.
